ABSTRACT

The rapid generation of large amounts of information about the coronavirus SARS-CoV-2 and the disease COVID-19 makes it increasingly difficult to gain a comprehensive overview of current insights related to the disease. With this work, we aim to support the rapid access to a comprehensive data source on COVID-19 targeted especially at researchers. Our knowledge graph, COVIDPUBGRAPH, an RDF knowledge graph of scientific publications, abides by the Linked Data and FAIR principles. The base dataset for the extraction is CORD-19, a dataset of COVID-19-related publications, which is updated regularly. Consequently, COVIDPUBGRAPH is updated biweekly. Our generation pipeline applies named entity recognition, entity linking and link discovery approaches to the original data. The current version of COVIDPUBGRAPH contains 268,108,670 triples and is linked to 9 other datasets by over 1 million links. In our use case studies, we demonstrate the usefulness of our knowledge graph for different applications. COVIDPUBGRAPH is publicly available under the *Creative Commons Attribution 4.0 International* license.

Background & Summary

The number of papers pertaining to SARS-CoV-2 and COVID-19 has surged over the last few months, making it hard to keep track of the latest research findings on the subject matter. Hence, the Allen Institute initiated a growing corpus of publications about COVID-19 called CORD-19¹, which is updated on a regular basis. While the CORD-19 dataset provides the extracted full texts and corresponding licenses, it is still difficult to consume for end users and applications. For example, the data is available as one download (see <https://www.semanticscholar.org/cord19/download>). Hence, users first need to download the dataset and carry out some processing (e.g., some form of information retrieval) to get the information they desire. The integration of insights from different sources, which is of central importance in scientific research, cannot be carried out on the dataset directly. Moreover, the data being available in textual form makes it difficult to query using a structured query language such as SQL or SPARQL.

A growing number of research labs are hence building upon CORD-19 to make the data more amenable to automated processing. Table 1 gives an overview of existing datasets pertaining to COVID-19. Some datasets such as WIKIDATA SCHOLIA only contain a small subset of the publications available as CORD-19. Other knowledge graphs about COVID-19 focus exclusively on case statistics instead of scientific publications (e.g., COVID-19 by STKO Lab) or text mining on the CORD-19 dataset without providing much information about the content present in the publications (e.g., COVID19-KG by Blender Lab and CORD-19-ON-FHIR). Our goal differs from that of other COVID-19-related datasets: We aim to provide a comprehensive RDF representation of the CORD-19 data and include Natural Language Processing (NLP) results on the data to facilitate the development of intelligent search engines, domain-specific conversational AIs and structured machine learning solutions for COVID-19.

In this paper, we present COVIDPUBGRAPH, a comprehensive RDF knowledge graph of COVID-19 based on CORD-19. Our dataset follows the Linked Data lifecycle². We provide a detailed representation of the COVID-19 publications in RDF including properties like publication title, authors names and their institutions, paper sections (e.g., abstract, introduction, body, discussion, etc.) and annotated references (e.g., references to figures). Resources such as authors and named entities augment the original data and make it easier to process for the sake of question answering and machine learning. All resources in the dataset are dereferenceable HTTP IRIs, which can be accessed via LODVIEW (<https://lodview.it/>) or via the dataset's SPARQL endpoint (<https://covid-19ds.data.dice-research.org/sparql/>). In addition, we link our dataset to the biomedical entities in other relevant datasets (e.g., DRUGBANK, SIDER, KEGG).

Our knowledge graph also abides by the FAIR principles³: It is *findable* by virtue of being annotated with rich metadata and indexable by search engines. We make it *accessible* by providing our data via an

39 RDF dump download (<https://hobbitdata.informatik.uni-leipzig.de/COVID19DS/archive/>), a
40 SPARQL endpoint as well as dereferenceable individual resources. For example, see (<https://covid-19ds.data.dice-research.org/resource/4bf4b71883a26d15dcc13b2800ec470b99764956>). We make it *interoperable* by employing standard
42 vocabularies, e.g., for authors, papers, and sections within papers, as well as through the aforementioned links to 9 knowledge
43 graphs including CORD19-NEKG, CORD-19-ON-FHIR as well as COVID-19-LITERATURE (see Table 2). We make it
44 *reusable* by associating the data with clear provenance and licensing information as well as by reusing popular vocabularies
45 such as NIF and Fabio ourselves.

46 Potential use cases of our knowledge graph include:

- 47 • Finding papers about certain biomedical entities, e.g., drugs, side effects, genes, or proteins.
- 48 • Discovering links between specific genome subsequences and drugs.
- 49 • Training explainable machine learning models by running structured machine learning on selected named entities (e.g.,
50 drug names) to find similar drugs for clinical trials. The models can be trained with DL-Learner⁴, EvoLearner⁵, or
51 DRILL⁶ and they learn class expressions in description logics based on the publication graph (e.g., drugs investigated by
52 similar authors or in similar articles). The class expressions are comprehensible by domain experts.
- 53 • Supporting scientometric research on various aspects related to COVID-19 publications, such as international collabora-
54 tion trends⁷ and peer review trends⁸, which would be informative for policy-makers and the scientific community.

55 Methods

56 Knowledge graphs on the field of COVID-19 can be divided by their topics covered: publications, biomedical entities, and case
57 statistics.

58 **Knowledge Graphs of Publications.** Most knowledge graphs of COVID-19 publications are based on the COVID-19 Open
59 Research Dataset (CORD-19) by the Allen Institute¹. The CORD-19 dataset is based on papers and preprints from Semantic
60 Scholar. Papers in CORD-19 are sourced from PubMedCentral (PMC), PubMed, the World Health Organization’s Covid-19
61 Database, and preprint servers bioRxiv, medRxiv, and arXiv¹. While CORD-19 contains the full texts of scientific publications,
62 it does not adhere to FAIR principles³, e.g., it is only available via download and does not use common vocabularies. The two
63 knowledge graphs most closely related to ours are CORD19-NEKG⁹ and COVID-19-LITERATURE¹⁰. However, neither of
64 them provides comprehensive metadata about the publications, and neither provides fine-granular information pertaining to
65 the publications (e.g., section information). An alternative to CORD-19 is the Lens dataset on COVID-19¹¹. Lens contains
66 metadata about scientific publications on COVID-19. However, it is only available as one big download (in JSON format).
67 The Covidgraph project (<https://covidgraph.org/>) aims to utilize the dataset. However, at the time of writing, the
68 proposed CovidPubGraph has not been released yet, making it hard to compare it to other knowledge graphs. To enable
69 interoperability, we link our dataset to other datasets such as the CORD19-NEKG.

70 **Knowledge Graphs of Biomedical Entities.** Most works utilizing CORD-19 focus on extracting named entities^{9,10,12,13}
71 such as genes, drugs, and proteins and linking them to existing knowledge bases such as DBpedia. For doing so, established tools
72 such as DBpedia Spotlight¹⁴ and Entity Fishing (Wikidata) (<https://github.com/kermitt2/entity-fishing/>)
73 are used. Alternatively, novel tools for recognizing biomedical entities on CORD-19 are also developed^{15,16}. Noteworthy is
74 also the work by Zhou, Y. *et al.*¹⁷, in which a network of genes, proteins, and viruses are proposed. The network is based on
75 pre-existing biomedical databases (e.g., DRUGBANK, Therapeutic Target Database, and BINDINGDB) and does not cover the
76 latest research findings. Still, such biomedical knowledge graphs might be employed to identify promising treatment options
77 such as repurposing existing drugs or developing novel drugs regardless of the underlying construction methodology. We
78 perform named entity recognition on CORD-19 and link the discovered entities to other biomedical RDF databases such as
79 DRUGBANK¹⁸ (drugs), SIDER¹⁹ (side effects), and KEGG²⁰ (genes), thus making our dataset more amenable to tasks such as
80 machine learning based on entities.

81 **Knowledge Graphs of Case Statistics.** Another class of knowledge graphs focuses on the case statistics of novel COVID-19
82 virus²¹, e.g., subdivided by region and based on the Dashboard data by the John Hopkins University.

83 Data Records

84 RDF Data Model Design

85 The ontology behind our knowledge graph was derived from the source from which it was extracted, i.e., the full-
86 texts of publications provided as part of the CORD-19 dataset. The ontology was designed to enable search, ques-
87 tion answering and machine learning. At the time of writing, our dataset is based on CORD-19 version 2021-11-08

```

88 (<https://www.semanticscholar.org/cord19/download>). Our conversion process is implemented in *Python*
89 3.6 with *RDFLib* 5.0.0 (<https://github.com/RDFLib/rdfliib>). We make our source code publicly available
90 (<https://github.com/dice-group/COVID19DS>) to ensure the reproducibility of our results and the rapid con-
91 version of novel CORD-19 versions. One version of the generated RDF dataset can be found at Zenodo²².

92 **RDF Namespaces**

93 To facilitate the reusability of our knowledge graph, we represent our data in widely used vocabularies and namespaces as
94 shown in listing 1.

95 **RDF Data Model**

96 Figure 1 shows important classes (e.g., papers, authors, sections, bibliographic entries, and named entities) as well as predicates
97 (e.g., first name, last name, license).

98 **Papers.** We represent bibliographic information of papers using four vocabularies: bibo, bibtex, fabio, and schema (see
99 namespaces above). Important attributes include the title, PMID, DOI, publication date, publisher, publisher URI, license and
100 authors. For each paper, we store provenance information. In particular, our code allows the reference to the original CORD-19
101 raw files as well as the time when we generate the resource. The URIs of our generated `Paper` resources follow the format
102 <https://covid-19ds.data.dice-research.org/resource/<paperId>> where `<paperId>` is the unique
103 paper id within the CORD-19 dataset.

104 **Authors.** Authors are represented in FOAF (<http://xmlns.com/foaf/spec/>). Important attributes include the first,
105 middle, and last names as well as mail addresses and institutions.

106 **Sections.** Papers are further subdivided by section and the corresponding information is expressed in the SALT ontology²³.
107 We keep track of a set of predefined sections including Abstract, Introduction, Background, Related Work,
108 Preliminaries, Conclusion, Experiment and Discussion. In case another section heading appears in the paper,
109 we assign it to the default section Body. We further subdivide a section using `cvdo:hasSection`. An example is given in
110 Listing 3.

111 **References.** References to other sections, figures and tables in the text are resolved and stored as RDF using `Bibref`.
112 Important attributes are the anchor of the reference (e.g., the number of the section, figure, or table), its source string in the
113 text (`nif:referenceContext`) along with its position in the text (`nif:beginIndex`, `nif:endIndex`) as well as the
114 referenced object (`its:taIdentRef`) which might be a paper (`BibEntry`), a figure (`Figure`), or a table (`Table`).

    cvdr:pmc1616946_Section3, cvdr:pmc1616946_Section4,
    cvdr:pmc1616946_Section5, cvdr:pmc1616946_Section6 .
```

Listing 3. Example section representation.

```
cvdr:pmc1616946_Section1 a sdo:Section ;
    nif:isString "The standard triplet readout of the genetic code can be reprogrammed by signals in the
    mRNA to induce ribosomal frameshifting [reviewed in (1-3)]. Generally, the resulting trans-frame
    protein product is functional and may in some cases be expressed in equal amounts to the product
    of standard translation. This elaboration of the genetic code (4,5) demonstrates versatility in
    decoding." ;
    bibtex:hasTitle "INTRODUCTION" .
```

115 **Named Entities.** As machine learning and question answering often rely on named entities and their locations in
116 texts, we annotate CORD-19 papers accordingly and represent this information with the NIF 2.0 Core Ontology
117 (<https://persistence.uni-leipzig.org/nlp2rdf/ontologies/nif-core/nif-core.html>). Fur-
118 ther details of our entity linking process are described in [Linking Section](#).

119 **RDF Example Resource.** Listing 2 provides an example of a paper represented as an RDF resource.

120 Listing 3 shows an example of a section represented in RDF. Each section is linked to its text string via `nif:isString`
121 and its title via `bibtex:hasTitle`.

122 If a section includes references to other papers, figures or tables (e.g., (1-3), (4, 5), Figure1A, Fig.1, etc.), we
123 represent a reference in RDF as follows: We represent the anchor of the reference with `nif:anchorOf` (e.g., the number of a
124 figure), the start position of the reference with `nif:beginIndex`, the end position of the reference with `nif:endIndex`,
125 the source section of the reference with `nif:referenceContext`, and the referenced target with `its:taIdentRef`
126 (e.g., a bibtex entry, figure or table). An example is shown in Listing 4. Listing 5 shows an example of provenance information.

Listing 4. Example of a reference to a paper and its associated bibtex entry.

```
cvdr:PMC1616946_Section1_B1_1 a nif:Phrase ;
  nif:anchorOf "1" ;
  nif:beginIndex "140"^^xsd:nonNegativeInteger ;
  nif:endIndex "141"^^xsd:nonNegativeInteger ;
  nif:referenceContext cvdr:PMC1616946_Section1 ;
  its:taIdentRef cvdr:PMC1616946_B1_1 .

cvdr:PMC1616946_B1_1 a bibtex:Entry ;
  bibtex:Inbook "159-183" ;
  bibtex:hasAuthor cvdr:DMDunn, cvdr:JFAtkins,
    cvdr:RBWeiss, cvdr:RFGesteland ;

  prov:wasDerivedFrom
    "https://ai2-semantic-scholar-cord-19.s3-us-west-2.amazonaws.com/latest/document_parses.tar.gz" .
```

127 Linking

128 We link our dataset to other data sources to ensure its reusability and integrability as well as to improve its use for search,
129 question answering and structured machine learning. We generate links from our paper and author resources to publicly
130 available related knowledge bases. Moreover, we extract named entities related to diseases, genes, and cells from all converted
131 papers and link them to three external knowledge bases.

132 **Linking Publications, Authors and Institutes.** We link *publications* in our knowledge graph to six other datasets using the
133 `owl:sameAs` and `rdfs:seeAlso` predicates (see top six rows of Table 2). To the best of our knowledge, those six datasets
134 are the most relevant RDF datasets that deal with the same publication data. We leave it to future work to link our dataset to
135 non-RDF datasets such as COVID19-KG¹² and WIKIDATA SCHOLIA²⁴.

136 CORD19-NEKG and our dataset use the same CORD-19 `paperId` making the linking process straightforward. For
137 LITCOVID, we use the PubMed Central Id (PMC-id) that is provided as part of CORD-19. For COVID-19-LITERATURE and
138 CORD-19-ON-FHIR, we employ `sha` hash values from CORD-19. Moreover, we link our dataset to the publications' JSON
139 files in CORD-19-ON-FHIR with the predicate `rdfs:seeAlso`. Listing 6 shows an example of linked publications from our
140 dataset COVIDPUBGRAPH to CORD19-NEKG and LITCOVID.

141 We link our resources of both our *authors* and *institutes* to the *Microsoft Academic Knowledge Graph* (MAKG)²⁵ using
142 the latest version of our link discovery framework LIMES²⁶. For linking the *authors*, LIMES is configured to discover
143 `owl:sameAs` links between our instances of `foaf:Person` and Microsoft's `makg:Author`. For linking the *institutes*,
144 we look for links between instances of type `dbo:EducationalInstitution` from our knowledge graph and MAKG's
145 resources of type `makg:Affiliation`. LIMES configuration files for linking authors and institutes are available as part of
146 our source code (<https://github.com/dice-group/COVID19DS>).

147 **Linking Named Entities.** We apply entity linking to connect entities derived from the sections of papers to other
148 knowledge bases. This process comprises two steps: (1) entity extraction and (2) entity linking. For the ex-

Listing 6. An example of a linked publication.

```
cvdr:pmc1616946 owl:sameAs inria:PMC1616946,  
  ncbi:PMC1616946 .
```

Listing 7. Entity linking example.

```
cvdr:PMC6979267_Section104#char=477,487
  a          nif:RFC5147String , nif:String, nif:Context ;
nif:beginIndex  "477"^^xsd:nonNegativeInteger ;
nif:endIndex    "487"^^xsd:nonNegativeInteger ;
nif:referenceContext  cvdr:PMC6979267_Section104 ;
nif:anchorOf      "folic acid" ;
itsrdf:taIdentRef  sider:5471bbbf1df9a8e21e95c5074a5a8717 , kegg:C00504 , drugbank:DB00158 .
```

149 traction step, we use SCISPACY²⁷ in version 0.2.4 in conjunction with the model `en_ner_bionlp13cg_md`
150 (<https://github.com/allenai/scispacy>) which allows the extraction of biomedical entities such as diseases,
151 genes and cells. SCISPACY is a specialized NLP library based on the spaCy library (<https://spacy.io/>). The NER
152 model in spaCy is a transition-based chunking model that represents tokens as hashed embedded representations of the prefix,
153 suffix, shape and lemmatized features of individual words²⁷.

154 For the linking step, we adapt the entity linking framework MAG²⁸ to link our extracted resources to the three
155 knowledge bases SIDER¹⁹, KEGG²⁰ and DRUGBANK¹⁸—using their RDF versions provided by the BIO2RDF project
156 (<https://bio2rdf.org/>). We adapt MAG by creating a search index for each of the external knowledge bases
157 and running MAG once per knowledge base. The output is a set of entities in the NLP Interchange Format (NIF)
158 (<https://persistence.uni-leipzig.org/nlp2rdf/>). In Listing 7, we provide an example for the named entity
159 “*folic acid*”.

160 Automated generation of COVIDPUBGRAPH

161 COVID-19 uploaded new data almost every day for the second half of 2020. Due to this fact, we have to automate the process of
162 updating our knowledge graph. To this end, we developed a pipeline to automate the entire process, which can be found in
163 Figure 2. This pipeline contains several steps:

- 164 1. **Crawling.** We start by crawling the most recent version as a zip file from the COVID-19 website, which includes a CSV
165 metadata file and JSON parsed full texts of scientific papers about the coronavirus.
- 166 2. **RDF conversion.** Then, we convert the COVID-19 data into an RDF knowledge graph with a Python script using the
167 RDFLib library (<https://github.com/RDFLib/rdfliib>).
- 168 3. **Linking.** We integrate the AGDISTIS library (<https://github.com/dice-group/AGDISTIS>) into the gen-
169 eration process to extract and link the named entities from abstracts of the scholarly articles. Moreover, we carry out the
170 entity linking tasks (i.e., link *publication* and *authors* to other datasets) by making use of the link discovery framework
171 LIMES (<https://github.com/dice-group/LIMES>).
- 172 4. **KG Update.** We upload the new version of COVIDPUBGRAPH dumps into the HOBBIT server
173 (<https://hobbitdata.informatik.uni-leipzig.de/COVID19DS/archive/>) as well as to the
174 Virtuoso triple store (<https://hub.docker.com/r/openlink/virtuoso-opensource-7>).

175 Starting from 2021, COVID-19 publishes new data only every two weeks. Therefore, we keep our KG up-to-date by crawling
176 the new version of the COVID-19 dataset biweekly. Then, we follow the KG creation procedure presented in Figure 2. As the
177 dataset is still not too big to be regenerated, we regenerate the complete dataset biweekly. Still, having an automatic incremental
178 update is part of our future plans.

179 Technical Validation

180 Representing COVID-19-related publications as RDF promises to facilitate many applications and use cases—some of which
181 we outline in this section.

182 **Updating the dataset.** An example of how the data are constantly updated is provided in Table 3, where we provide details
183 about the growing number of different resource types across successive versions of our knowledge graph. As we trust the data
184 provider, i.e. the Allen Institute, we do not do any further data cleaning than the pipeline introduced in Figure 2. Moreover, the
185 number of generated links to other external datasets within our linking (see Table 2), provides further evidence of the quality of
186 the data.

Listing 8. List all paper URIs written by the author “Ian Mackay.”

```
SELECT DISTINCT ?paper
WHERE {
  ?paper bibtex:hasAuthor ?author .
  ?author foaf:firstName "Ian" .
  ?author foaf:lastName "Mackay" .
}
```

Listing 9. List the top 10 papers-URIs with the most number of authors.

```
SELECT ?author count( * ) as ?cnt
WHERE {
  ?paper a swc:Paper .
  ?paper bibtex:hasAuthor ?author .
}
ORDER BY DESC(?cnt)
LIMIT 10
```

187 **Data Retrieval.** While our base dataset CORD-19 contains a significant number of publications, they are not represented in a
188 format optimized for retrieval.

189 By providing COVIDPUBGRAPH in RDF with a well-defined ontology, we enable the easy retrieval of data with structured
190 query languages such as SPARQL. For example, Listing 8 shows a query to retrieve all papers written by the author “Ian
191 Mackay.” Another query to retrieve the top 10 papers in terms of their number of authors is provided in Listing 9.

192 Using SPARQL queries, we carried out some random checks of the duplicate articles and authors, which resulted in no
193 duplicates. This could be a direct consequence of the high quality of the original CORD dataset. Still, doing a full KG
194 deduplication task is part of our future work.

195 **Interoperability using NIF.** Using the interoperability capabilities provided by NIF, it is easy to query all occurrences of a
196 certain text segment within the whole dataset and still know exactly where each mention occurs. For example, in Listing 10, we
197 provide a SPARQL query to list all papers where “folic acid” is mentioned with their respective sections.

198 **Information Aggregation.** Linking our dataset to other RDF datasets adds a considerable amount of value. For example,
199 Microsoft Academic Knowledge Graph (MAKG) covers more than 209 million publications (<http://ma-graph.org/>)
200 and our interlinking enables the retrieval of an author’s citation count (Listing 11).

201 Usage Notes

202 Table 4 summarizes all technical details of our dataset pertaining to its availability.

203 **Persistent URIs.** All our resources are served from one of our servers via persistent URIs. The resource will be maintained by
204 the DICE research team (<https://dice-research.org>) as part of the lab’s HOBBIT dataset efforts²⁹. A 100TB-Server
205 maintained by the Paderborn university’s computing centre will host the datasets.

206 **Resource Dereferencing.** We employ LODVIEW (<https://lodview.it/>) for dereferencing our dataset URIs and
207 allowing users to conveniently browse HTML pages. Figure 3 shows an example of a resource being served by LODVIEW.

Listing 10. List all papers and sections mentioning “folic acid.”

```
SELECT DISTINCT ?paper ?section
WHERE {
  ?s nif:anchorOf "folic acid" .
  ?s nif:referenceContext ?section .
  ?body cvdo:hasSection ?section .
  ?paper cvdo:hasBody ?body .
}
```

Listing 11. SPARQL example for retrieving more data via interlinking with MAKG.

```
SELECT DISTINCT ?name ?paperCount ?citationCount WHERE {  
  ?paper a swc:Paper.  
  ?paper bibtex:hasAuthor ?author .  
  ?author owl:sameAs ?maAuthor.  
  
  SERVICE <http://ma-graph.org/sparql> {  
    ?maAuthor makg:paperCount ?paperCount .  
    ?maAuthor makg:citationCount ?citationCount.  
    ?maAuthor foaf:name ?name.  
  }  
}  
LIMIT 100
```

208 **Dump Files.** We provide dump files of our dataset for download. The generated RDF datasets are located on our HOB-
209 BIT storage (<https://hobbitdata.informatik.uni-leipzig.de/COVID19DS/archive/>) and archived on
210 Zenodo (<https://zenodo.org/record/4650261>).

211 **SPARQL Endpoint.** We publicly serve COVIDPUBGRAPH via a SPARQL endpoint
212 (<https://covid-19ds.data.dice-research.org/sparql>).

213 Code availability

214 Our source code to generate the new versions of our knowledge graph is publicly available at
215 <https://github.com/dice-group/COVID19DS> and is maintained in parallel with the knowledge graph.

278 Acknowledgments

279 This work has been supported by the German Federal Ministry of Economics and Technology (BMWI) project RAKI (GA
280 no. 01MD19012D), the EU H2020 project KnowGraphs (GA no. 860801) as well as the BMVI projects LIMBO (GA no.
281 19F2029C) and OPAL (GA no. 19F2028A).

282 Author contributions statement

283 Svetlana Pestryakova carried out the main RDF data transformation and linking tasks. Daniel Vollmers deployed the NLP
284 algorithm for the named entity extraction. Mohamed Ahmed Sherif analysed the data and conceived the work, Stefan Heindorf
285 prepared the initial manuscript. Muhammad Saleem enhanced the manuscript. Diego Moussallem enhanced the manuscript.
286 Axel-Cyrille Ngonga Ngomo supervised the work. All authors contributed to the text of the article, read and approved the final
287 manuscript.

288 **Competing interests**

289 The authors declare no competing interests.
